

Shobdon Central — Weather Feed Setup

Instructions for the PC that connects the weather station to Shobdon Central (“PC2”)

What this does

A small script reads the live weather display on the local network and sends it to Shobdon Central every minute, so the clubhouse dashboard and pilots browsing from home see current conditions. It does not change, install, or read anything else on this computer.

Setup (do this once)

1. Download two files

From the Weather Config page, download both **capture-weathercentral.ps1** and **install-weather-capture-autostart.bat**.

2. Save them together

Put both files in the same folder on this PC — anywhere is fine, e.g. Documents. They need to sit side by side.

3. Run the installer once

Double-click **install-weather-capture-autostart.bat**. A black window will appear, show a short setup message, and then say *DONE*. You can close it after that.

4. Leave it alone

That's it — the capture will now start automatically every time this PC is logged into, running quietly in the background. No further action is needed.

How to check it's working

Open the **View Capture Logs** link on the Weather Config page. If it's working, you'll see a “Latest” entry with a timestamp from the last minute or two, updating continuously. That confirms data is reaching Shobdon Central.

If it doesn't seem to be working

Try the **Refresh PC2 Now** button on the Weather Config page first — it asks this PC to send an immediate capture, and the Capture Logs page will show whether that arrived within about 15–30 seconds. If nothing arrives after a couple of tries, please get in touch with whoever manages this system for you, including a screenshot of the Weather Config page and, if possible, of the black window from step 3 if it's still open.

This computer only ever sends the weather page contents to Shobdon Central — it does not receive commands, does not get remotely controlled, and nothing described here requires administrator rights beyond running the one installer above.
